

## **Combinatorial Exploration: An Algorithmic Framework for Enumeration**

Michael H. Albert (University of Otago), Christian Bean, (Keele University), Anders Claesson (University of Iceland), Émile Nadeau (Reykjavik University), Jay Pantone\* (Marquette University), Henning Ulfarsson (Reykjavik University)

Combinatorial structures are ubiquitous throughout mathematics. Graphs, permutations, words, and other such families of combinatorial objects often play a central role in work from many different fields. The study of enumerative combinatorics is concerned with the elucidation of structural properties of these families, including counting, classification, and limiting behavior.

Combinatorial Exploration is a framework that unifies the often ad-hoc methods used in enumerative combinatorics. In this talk we'll explain how Combinatorial Exploration works, how it can be automated, and how it has been applied to the study of pattern-avoiding permutations to prove new results and reprove dozens of old ones. We will also discuss the new web database PermPAL (<https://permpal.com>) that catalogs these results.

Keywords: algorithmic enumeration, experimental combinatorics, permutation patterns
