Zero forcing is a graph coloring process in which a set of initially blue vertices force the remaining vertices in the graph to be colored blue after repeated applications of a color change rule. Leaky forcing is a fault-tolerant variant of zero forcing in which some set of  $\ell$  vertices, called leaks, are forbidden from forcing. The  $\ell$ -leaky forcing number is the size of the smallest set of initially blue vertices for which the graph is successfully forced despite the placement of  $\ell$  leaks. In this talk, we will characterize the  $\ell$ -leaky forcing number for unicyclic graphs.

Keywords: Leaky forcing, zero forcing, unicyclic graphs
